

New World Order and the Final Frontier

Thomas Haeberle
Amateur Astronomers Association

Planets are principal components of the solar system, yet a modern definition is still elusive. Some base what a planet is on shape while others feel where an object forms is more important. There is no reason why two systems of classification can be used - one that groups objects into broad families based on their station within in the system and their dynamical dominance of their neighborhood were it formed. At the same time we can further break these objects down by class of objects based on physical characteristics.
